

Study Session of the City Council
Live Oak Council Chambers
9955 Live Oak Blvd., Live Oak, CA 95953

The Council may take up any agenda item at any time, regardless of the order listed. Action may be taken on any item on this agenda. Members of the public may comment on any item on the agenda at the time that it is taken up by the Council. Requests to speak on the item should be made to the Mayor at the time an item is discussed. We ask that members of the public come forward to be recognized by the Mayor and keep their remarks brief. Absent permission from the Mayor, comments will be limited to three (3) minutes.

Mayor – Gary A. Baland Vice Mayor – Steve Alvarado Council Member – Rob Klotz Council Member – Felicity Clark Council Member – Diane Hodges

 - 1. Master Drainage Study and Storm Drain Connection Fee
- D. ADJOURNMENT

DATE:

April 15, 2011

TO:

Mayor and Members of the City Council

FROM:

Jim Goodwin, City Manager

COUNCIL AGENDA STAFF REPORT

SUBJECT:

Completion of Master Drainage Study and Proposed Storm

Drain Connection Fee

RECOMMENDATION: Review only. No action required at this meeting

FISCAL IMPACTS:

Establish fees at appropriate levels based on build-out of the

2030 General Plan

A key implementation item for the new 2030 General Plan is the adoption of the completed Master Drainage Study and update of storm drain connection fees. The findings of the study and recommendations for the proposed fee will be reviewed in Study Session.

The attached presentation materials and Technical Memorandum from Doug Moore from West Yost Associates provides details for the discussion. Mr. Moore will be present to report on the findings and recommendations.

Following review at Study Session, adoption of the study and fees will be on the agenda for consideration at a future City Council meeting.

Respectfully Submitted,

Jim Goodwin City Manager

TECHNICAL MEMORANDUM

DATE: March 23, 2011

Project No.: 047-00-08-15.006

TO:

Jim Goodwin

City Manager, City of Live Oak, California

FROM:

Douglas T. Moore, R.C.E. #C58122

REVIEWED BY: Steven R. Dalrymple

SUBJECT:

City of Live Oak Recommended Storm Drainage Connection Fees

INTRODUCTION

West Yost Associates (West Yost) recently completed the Master Drainage Study (MDS) for the City of Live Oak (City) (March 2011). The MDS identified a Recommended Drainage Program (RDP) and presented estimates of the construction and capital costs of the RDP. This Technical Memorandum (TM) provides a recommended update of the City's storm drain connection fee based on the estimated total capital cost of the RDP. The City intends to update the storm drainage connection charges to provide funding for the capital projects that are planned in the MDS.

The City owns, operates and maintains a system of storm drainage facilities. The City currently charges a one-time "storm drain connection charge" to residential property of \$3,598 per acre or \$850 per residence and to commercial property of \$4,318 per acre. The City's master fee schedule also includes AB1600 development impact fees for flood control facilities of \$2,185 per dwelling unit for R1, R2, and R3; \$734 per dwelling unit for R4; and \$14,663 per acre for commercial and industrial land uses.

The proposed 2011 Storm Drain Connection Fee (SDCF) includes a future infrastructure component and an administrative charge component.

- Future infrastructure component This fee component covers the cost of the future infrastructure that is required for the future growth of the City. The estimated cost of the future infrastructure was developed in Table 14-2 of the MDS (a copy is provided in Appendix A of this TM). These future infrastructure costs include only the costs of projects that are needed for the future growth of the City. The future infrastructure costs do not include costs for infrastructure that is needed to solve existing flooding problems.
- Administrative charge component This fee component covers the costs for City staff to manage the Storm Drain Connection Fee Program.

Technical Memorandum March 23, 2011 Page 2

Presented in Table 1 is a summary of the recommended 2011 SDCFs by land use type. For low-density residential, small-lot residential and medium-density residential, the SDCF is established as a cost per dwelling unit. For all other land uses, the 2011 SDCFs are established as a cost per acre. Also included in Table 1 are the land use types from the existing City areas.

For the parks, civic, urban reserve, and buffer land uses, the 2011 SDCF was set to zero. Assessment of fees to the parks and civic land uses would result in the City assessing fees to the City, school district, Sutter County, or other government agencies, which would in turn have to pass the cost of these fees on to the public. Assessment of fees to the urban reserve and buffer land uses is inappropriate because these land uses do not result in development of the land nor cause an increase in the potential runoff.

Different land use types generate different runoff rates. For example, low-density residential areas have an imperious coverage of about 30 percent, meaning that about 30 percent of the land use area is covered with roads, houses, driveways, or other impervious surfaces. Commercial areas typically have an impervious coverage of about 85 percent. These impervious surfaces prevent rain from infiltrating into the ground, and therefore, impervious surfaces produce more total runoff volume than pervious areas such as lawns or landscape areas. Also, the impervious areas are usually constructed to drain more quickly than pervious surfaces. For example, house roofs are sloped to force runoff to quickly flow to the house gutters, the gutters convey the runoff to the downspouts, which often covey the water directly to the street gutters. However, rain falling on lawns is trapped among the blades of grass, and flows very slowly to the street gutters. Thus, impervious surfaces produce more total runoff and produce runoff at higher flow rates than pervious surfaces. The higher runoff rates require larger, more costly storm drain infrastructure to convey or detain the runoff. Therefore, land uses with higher impervious surface coverages should be charged higher storm drain connection fees than land uses with lower impervious surface coverages.

In this rate study, the differences in runoff volumes and rates for different land use types are accounted for by the use of Equivalent Drainage Dwelling Units (EDDUs) as explained below. For the future land use types, a single low-density residential unit is assigned a value of 1 EDDU. An average acre of low-density residential land use has 3.89 dwelling units, which is equal to 3.89 EDDUs. However, an acre of Community Commercial land use has 6.56 EDDUs. By developing EDDUs for each land use type, the costs of the stormwater infrastructure can be apportioned fairly among the various land uses.

The 2011 SDCFs were developed through the following steps:

- 1. Convert the expected land use coverage to EDDU density, and calculate the total EDDUs for each land use type within the future growth areas of the City and the parcels within the existing City that will develop in the future (Table 2).
- 2. Document the future infrastructure estimated costs associated with the future growth of the City (see Table 14-2 of the MDS reproduced in Appendix A of this TM).
- 3. Develop the total cost per EDDU for the infrastructure needed for the future growth of the City, including the costs associated with financing the future infrastructure (Table 3).

- 4. Spread the future infrastructure costs to each future land use type and calculate the future infrastructure component of the SDCF (Table 4).
- 5. Develop the 2011 SDCF by summing the future infrastructure component of the SDCF and a 2 percent administrative fee component (Table 1).

The process to derive the 2011 SDCFs is discussed in more detail below.

DEVELOPMENT OF EQUIVALENT DRAINAGE DWELLING UNITS FOR THE FUTURE GROWTH AREAS

The development of EDDUs for each land use type within the future growth areas of the City and the parcels within the existing City that will develop in the future is presented in Table 2. The future land uses are described and defined in Table LU-2 of the recently adopted City of Live Oak 2030 General Plan. The areas of each land use within the future growth areas of the City were developed and provided by AECOM. The parcels within the existing City that will develop in the future were also identified by AECOM. AECOM was the City's consultant for the preparation of the City of Live Oak 2030 General Plan. The residential land use dwelling unit density is the anticipated average density of each type of residential dwelling units. The dwelling unit density was also provided by AECOM, and falls near the middle of the range of potential densities presented in Table LU-2 of the *City of Live Oak 2030 General Plan*.

Table 2 develops the total EDDUs for the future growth areas of the City by land use type, as described below.

- The area of each land use type and dwelling unit density for residential development were provided by AECOM.
- The impervious percentages by land use type are from Table 7-1 of the MDS. The impervious percentage is the fraction of the land that is covered by impervious surfaces such as buildings, parking lots, roads (versus pervious coverage such as lawn or landscape areas).
- The pervious and impervious area C-values are from the City of Live Oak Public Works Improvement Standards. These values are roughly proportional to the expected runoff rate from the pervious and impervious land coverages.
- The area weighted composite C-value is the area weighted average of the pervious and impervious area C-values. For example composite C value for a Low Density Residential parcel is 0.48.
- The ratios of composite C-value to the low density residential C-value is calculated for each land use type. This ratio estimates the relative peak runoff rate for each land use in comparison to the runoff rate from a low-density residential dwelling unit. For example, one acre of commercial mixed use land use is expected to produce a peak runoff rate about 1.69 times the runoff from one acre of low-density residential land use.
- The EDDU density for each land use type is calculated by multiplying the C-value ratio by 3.89 EDDUs per acre.

Technical Memorandum March 23, 2011 Page 4

• The total EDDUs is calculated by multiplying the EDDU density by the area for each land use type. The parks and open space, civic, reserve, and buffer land uses represent undeveloped lands or public lands (from a City development/growth perspective) which will not pay for draining infrastructure; thus these land uses were assigned no EDDUs in Table 2.

CALCULATION OF THE FUTURE INFRASTRUCTURE COMPONENT OF THE SDCF

The storm drainage infrastructure required for buildout of the 2030 General Plan is identified in the MDS prepared for the City by West Yost (March 2011). The RDP facilities are shown on Figure 14-1A of the MDS. The capital cost of the RDP was developed in Table 14-2 of the MDS, and the total capital cost was estimated to be \$39.98 million. Copies of Figure 14-1A and Table 14-2 of the MDS are provided in Appendix A of this TM.

For this rate study, it has been assumed that the capital cost of the future infrastructure (\$39.89 million) will be financed through a sale of bonds. The financing costs of the bonds is shown in Table 3. This financing plan results in a net present value of the bond debt service of about \$61.43 million. If this present value is shared by the future EDDUs, the cost is \$3,682 per EDDU, as shown in Table 3.

In Table 4, the future financed infrastructure cost is assigned to the various land use types in the future growth areas of the City. The costs are assigned based on the total EDDUs in each land use type, at a cost of \$3,682 per EDDU. The future infrastructure component of the SDCF is then calculated by dividing the total cost for each land use type by the acreage of that land use type. For example, the future infrastructure cost component of the SDCF for the commercial mixed use land use is \$24,170 per acre.

For the low-density residential, smaller-lot residential, and medium-density residential land uses, the net value per dwelling unit is shown because for these land uses the SDCF is a fee per dwelling unit. For these land uses, the SDCF per dwelling unit is calculated in Table 4 by dividing SDCF per acre by the average dwelling unit density for each of these land uses. For example, the future infrastructure component of the SDCF for smaller-lot residential dwelling units is \$2,764 per dwelling unit.

CALCULATION OF THE SDCF

The recommended SDCFs by land use type are summarized in Table 1. The proposed SDCF includes the future infrastructure component, and an administrative charge component, which is 2 percent of the future infrastructure component. For example, the SDCF for commercial mixed use land is \$24,654 per acre. The SDCF for a smaller-lot residential dwelling units is \$2,819 per dwelling unit.

Land use acreges were provided by the City's General Plan update consultant.

Impervous Percentages are from the Table 7-1 of the Master Draiange Study prepared for the City of Live Oak (March 2011). C-Values are from the City of Live Oak Public Works Improvement Standards (June 2003).

For parks and open space, civic, urban reserve, and buffer land uses, the total EDDUs was set to zero to eliminate collection of stormwater Connection fees from these land uses.

City of Live Oak Master Drainage Study (MDS)

April 19, 2011

Background

Existing Problems

RD 777 Service Area Alternatives Evaluation

Recommended Project

Financial Evaluation

Background

Existing Problems

RD 777 Service Area Alternatives Evaluation

Recommended Project

Financial Evaluation

Background

Began as a MDS for RD 777 in 2005

Expanded Study to Support City's General Plan Update in 2008

ncreasing City or Agricultural Flooding Goal: Allow City to Grow Without

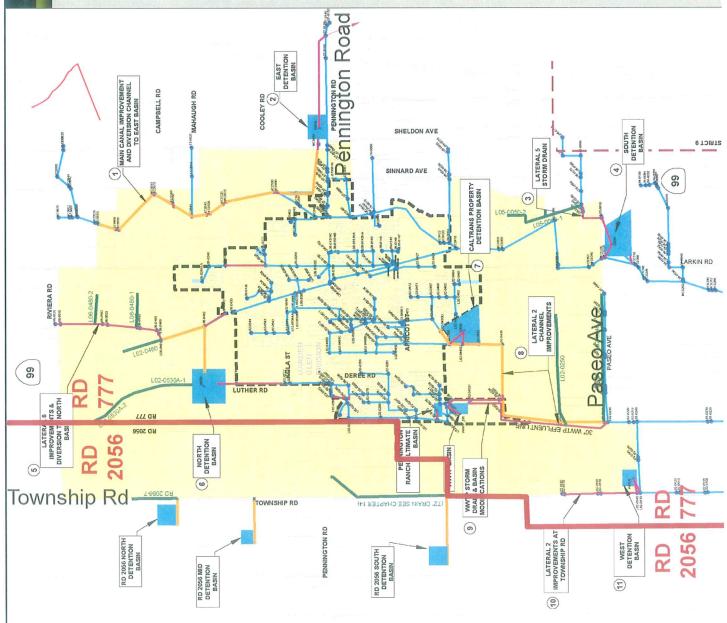

Developed Recommended Drainage Project

Seeking Adoption of MDS

RD 777 and RD 2056 Service Areas

Background

Existing Problems

RD 777 Service Area Alternatives Evaluation

Recommended Project

Financial Evaluation

Existing Problems

- 1. J Street South of Pennington Road
- 2. L Street Between Birch Street and Pennington Road
- 3. Highway 99 Flooding
- 4. De Ree Road and Luther School
- 5. Ditches West of P Street and South of Pennington Road

New Storm Drain Pipe Systems were Evaluated and Sized Cost of Storm Drains Estimated at \$5.5 million

Background

Existing Problems

RD 777 Service Area Alternatives Evaluation

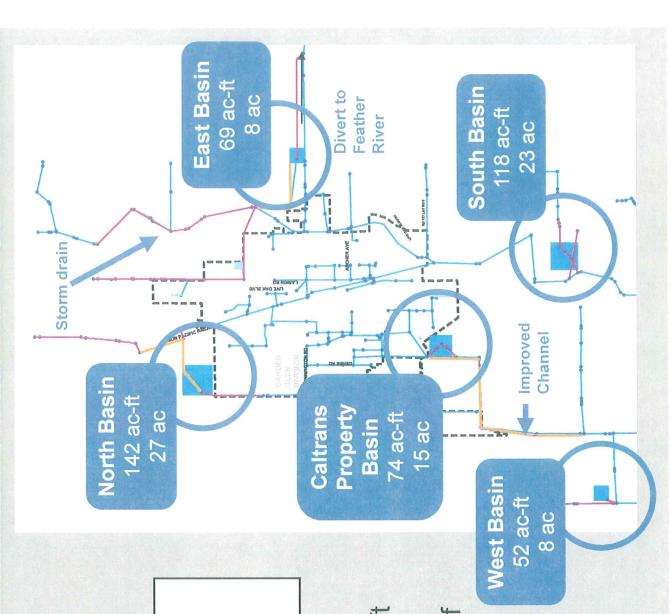

Recommended Project

Financial Evaluation

Alternative 1: Flood Control

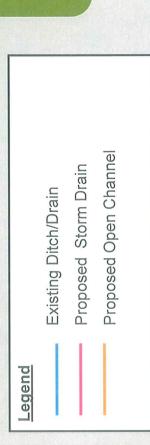

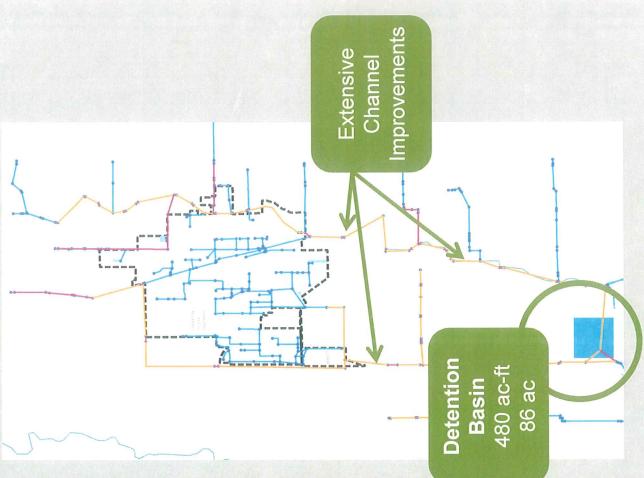

- 5 Detention Basins
- Total Storage: 455 ac-ft
- Total Area: 80 ac
- Divert NE Quadrant Runoff to Feather River
- Large Storm Drains & Channel Improvements Capital Cost: \$48 million

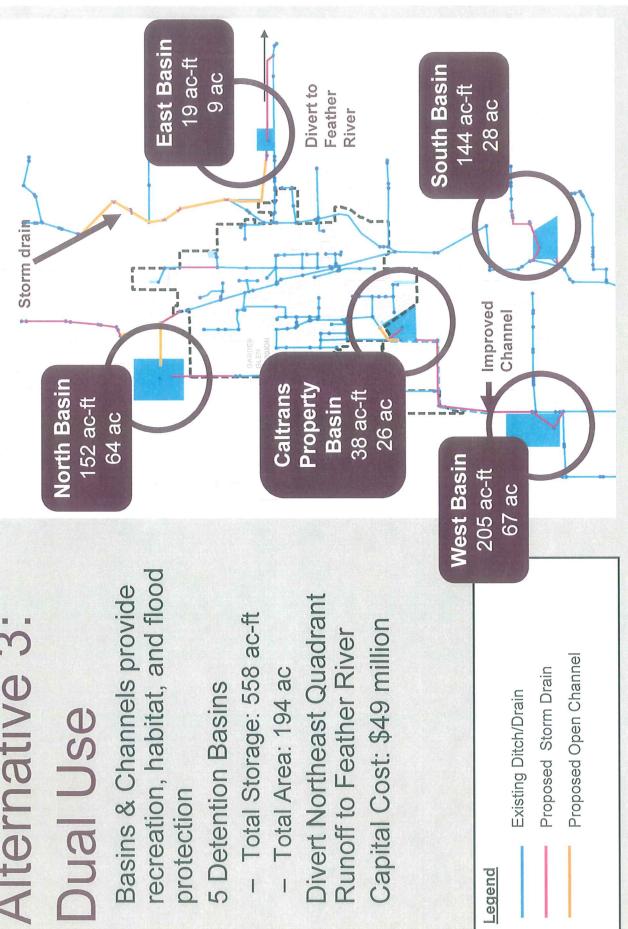

Alternative 2: Regional Detention Storage & Increased Channel Capacity

- Detention Basin
- Total Storage: 480 ac-ft
- Total Area: 86 ac
- Increased Channel Conveyance
- Capital Cost: \$66 million

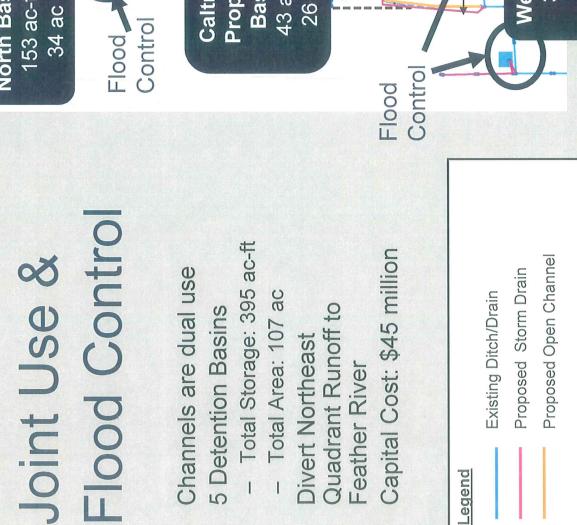

Alternative 3:

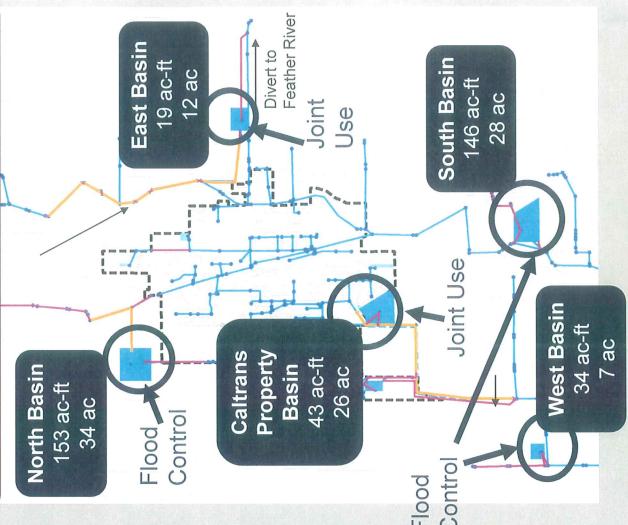

Alternative 4: Joint Use &

- 5 Detention Basins
- Quadrant Runoff to Divert Northeast

Recommended Alternative

Alternative Comparison Summary

ltem	Alt. 1	Alt. 2	Alt. 3	Alt. 4
Basin Volume (ac-ft)	455	480	558	395
Basin Area (acres)	80	86	197	107
Channel Area (acres)	33	90	53	54
Total Area (acres)	113	176	250	160
Pump Stations	3	0	_	2
Total Cost (\$, million)	48	99	49	45
